

5.5 Stock market prediction

In this problem, you will apply a simple linear model to predicting the stock market. From the course web site, download the files `nasdaq00.txt` and `nasdaq01.txt`, which contain the NASDAQ indices at the close of business days in 2000 and 2001.

(a) Linear coefficients

How accurately can the index on one day be predicted by a linear combination of the four preceding indices? Using only data from the year 2000, compute the linear coefficients (a_1, a_2, a_3, a_4) that maximize the log-likelihood $\mathcal{L} = \sum_t \log P(x_t | x_{t-1}, x_{t-2}, x_{t-3}, x_{t-4})$, where:

$$P(x_t | x_{t-1}, x_{t-2}, x_{t-3}, x_{t-4}) = \frac{1}{\sqrt{2\pi}} \exp \left[-\frac{1}{2} \left(x_t - a_1 x_{t-1} - a_2 x_{t-2} - a_3 x_{t-3} - a_4 x_{t-4} \right)^2 \right],$$

and the sum is over business days in the year 2000 (starting from the fifth day).

(b) Mean squared prediction error

For the coefficients estimated in part (a), compare the model's performance (in terms of mean squared error) on the data from the years 2000 and 2001. Would you recommend this linear model for stock market prediction?
